You can order the application for your church or individual ministry today!Many high-speed electronic applications such as data communications, networking, and computing utilize circuitry that operate at high voltages, e.g., 10-100 volts, but that require voltages that are compatible with lower operating voltages, e.g., 2-5 volts. Such circuits include transistor-transistor-logic (TTL) circuits. The TTL circuit typically includes a source of supply voltage for the output device. In systems that utilize the TTL circuit, it may be important that the circuit be packaged in a minimum number of parts that require a minimum of area on the printed circuit board. FIG. 1 illustrates a prior art TTL inverter 100 that utilizes six active components, i.e., two p-channel transistors 105 and 110, two n-channel transistors 115 and 120, and two diodes 125 and 130. The TTL inverter 100 is further coupled to a charge pump 135, such as a laterally diffused metal oxide semiconductor (LDMOS) transistor, that provides a positive supply voltage VCC to the inverter 100. As is known to those of ordinary skill in the art, the p-channel transistors 105 and 110 are often used as current sources that can be switched on and off by the logic states of the n-channel transistors 115 and 120, respectively, thereby producing a voltage differential between the inputs A and B. The output voltage of the inverter 100 is taken at the drain of the n-channel transistor 120. Since this is an n- b7e8fd1f5c8
